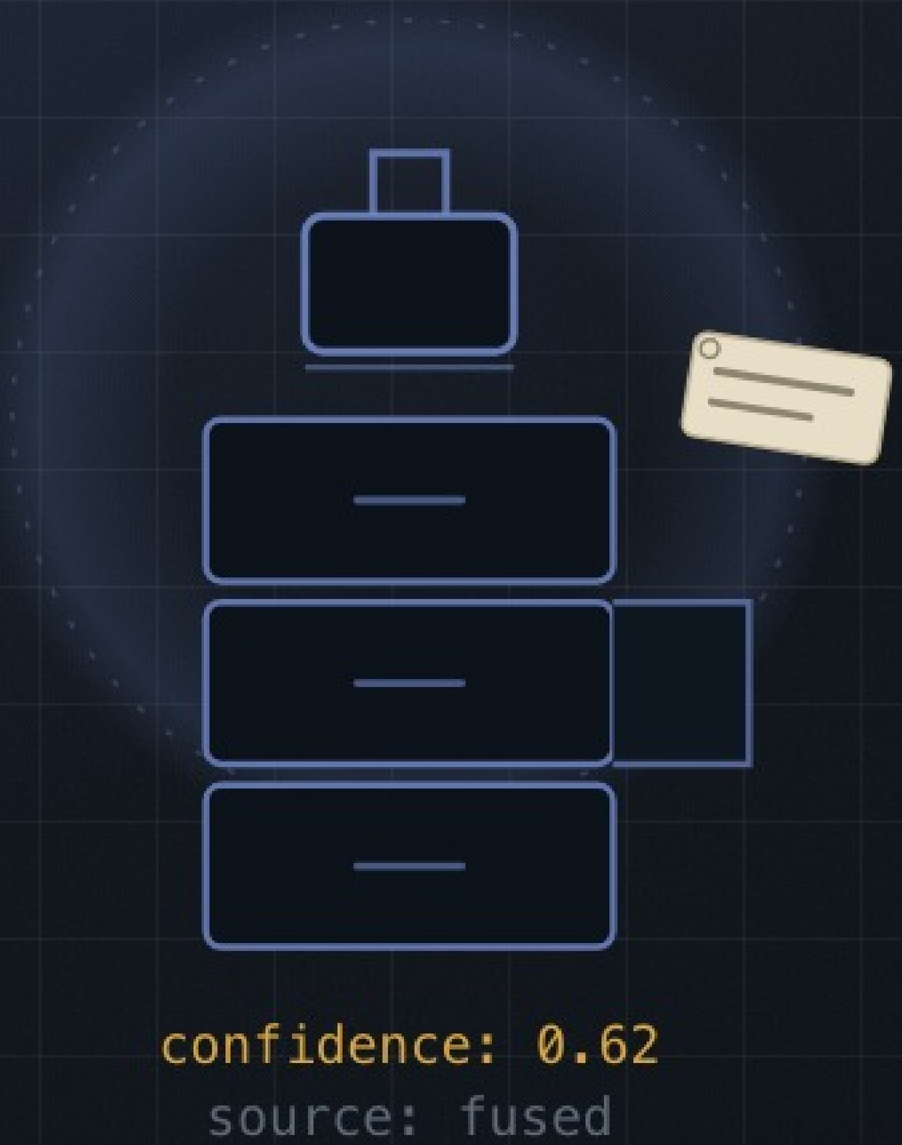
// CHAIN OF CUSTODY

The sensor knew. The column did not.

Every GPS reading arrives with an error estimate. Most schemas store the coordinate and bin the rest.

We threw it away on the way in.

It keeps every reading's papers



THE ARCHIVIST

exhibit 03

Provenance

Where it came from, how sure it was, what we already ruled about it. Nobody thanks the Archivist until a number is disputed, at which point it is the only reason there is an answer.

// THE SCHEMA

Design the row to carry doubt

```
@Entity
data class LocationData(
    val lat: Double,
    val lng: Double,
    val speed: Float,
    val date: Long,
)
```

// THE COLUMNS

What every row owes you

01 **The value**
lat, lng, distance, whatever you measured

02 **How wrong it might be**
accuracy radius, confidence, error bars

03 **Where it came from**
provider, sensor, model version, timestamp

04 **What you already concluded**
the verdict, so nobody re-litigates it

You cannot backfill confidence you **discarded**

Uncertainty does not get lost in the algorithm. It gets lost at write time, in the schema.

Add the columns before you need them.
