

// CHAIN OF CUSTODY

The sensor knew. Your schema didn't.

Every reading arrives with an
error bar.

Most tables store the value
and bin the rest.

// WHAT ARRIVES

More than a point

Android Location carries:
accuracy radius, provider,
bearing, altitude, timestamp.
It is telling you how much
to believe it.

// WHAT WE STORED

lat, lng,
speed,
date

Reasonable. Minimal.

Exactly what the feature
needed that week.

It also discarded the error
bar on every single write.

// MONTHS LATER

Questions you can't answer

Was this tracked well or badly?

Fused or raw GPS?

Was the device even moving?

Not an algorithm problem.

// THE FIX

Store the papers too

The reading.

How much to trust it and
where it came from.

And your own verdict:

isMock, isAbnormal, displacement.

// THE RULE

Design the row to carry doubt

Those columns are cheap.
Add them before you need them.
You cannot backfill confidence
you threw away at write time.
