

Tuning needed a release. So we stopped.

Every change needed a
code review, a release, and
a week of store rollout.

So we stopped tuning,
which is the worst possible
outcome.

A threshold is a hypothesis

confidence: 0.62
source: fused

THE ARCHIVIST

exhibit 03

Provenance

Constants are for things that cannot change, like the number of metres in a kilometre. A jitter threshold is a current best guess wearing a constant's clothes.

The Loopdown

swipe

One config object, not eighteen consts

Constants are for things that cannot change, like the number of metres in a kilometre. A jitter threshold is a current best guess wearing a constant's clothes.

Make tuning cheap

01 Gather them into one object
18 scattered `const val` became one `config`

02 Make it serialisable
now it can come from somewhere else

03 Then a settings change
tune without touching the algorithm

04 Then a server change
tune without shipping at all

Separate the algorithm from its parameters

A hypothesis needs to be cheap to revise. If tuning costs a release, people guess instead of measuring.

And then they defend the guess.
